

Digital Twin Earth

Coastal Processes and Extremes

Présentation Paris – 29 juin 2026

Antoine Mangin – ACRI-ST

Digital twin ?

Digital Twin : digital replica of phenomena or mechanisms (of environmental, societal, economical ... origins) with the help of all inputs parameters (causes) and outputs parameters (consequences)
This allows **evaluation of processes** between parameters and their **exploitation through scenarios**

Organisation of	Data	Harvesting, formatting, QC, merging, uncertainties estimates
What is the situation	Now	Derivation of processes between causes and consequences (deterministic modelling, statistical approach, AI, hybrid...) Evaluation of the processes quality/reliability/accuracy on a regular basis through continuous acquisition of data (link with Data)
What will be the situation	Next	Application of known scenarios (e.g. IPCC) to the processes, accounting for known reliability and accuracy
What could be the situation	If	Derivation of scenarios on extreme (and potentially unmet) causes Application of these scenarios to the processes, accounting for know reliability and accuracy

Coastal change – Happisburgh, Norfolk

Since the removal of a coastal defence section in 1999, 34 homes have crumbled into the water in Happisburgh because of coastal erosion.

Centre: Original coastal defences (1996).

Right: Recent headlines.

Coastal change – users requirements

Type	Environment
Goal	Decision support, risk management & communication
Interventions	System operation (e.g. beach nourishment, hard defences) & policymaking
Cost reduction	Disaster risk reduction, climate adaptation & biodiversity protection
System representation	Many systems (objects and large systems)
Timespan	Decades

Coastal flooding

Coastal flooding is one of the **most destructive natural hazards** with social, economic and environmental consequences.

Coastal flooding will become more challenging:

Relative sea-level rise and changes in storms & precipitation

Population growth and urban development in floodplains

Degradation of natural habitats that act as a buffer to flooding;

Ageing flood defence assets

Impact of Storm Ciara (Feb., 2020) on Saint Malo, France (Credit: EasyRideVideos)

Drivers of Coastal & Compound Flooding

$$\text{Total Water Level} = \text{MSL} + \text{tide} + \text{storm surge} + \text{wave setup} + \text{river input} + \text{rainfall/runoff} [+ \text{SLR}]$$

Methodology

- Chained modelling approach: Climate-Hydrologic-Hydraulic model
- Calibration & validation using in-situ data & multiple EO datasets
- What-if scenarios related to boundary conditions (from RCMs and storm surges) and/or river/floodplain geometry changes

Figure 2.2: Study area: River Severn (UK). Only the boundary condition in Bewdley is taken into account. Within the sub-catchment upstream of Bewdley (area of 4325 km²) a lumped hydrologic model is used to determine the input of the hydraulic model along the river Severn downstream. The dots represent the existing gauging stations where the performances of the DA framework are evaluated. The black square is the hydraulic domain where LISFLOOD-FP runs.

Leverage EO data

Climate Models and “What-if” Scenarios

Regional climate models: EURO-CORDEX archive (11 km, Europe) provide **precipitation** and **air temperature** projections, covering three Representative Concentration Pathways—RCP2.6 (stringent mitigation), RCP4.5 (moderate change), and RCP8.5 (severe change).

What-if scenarios:

- Users can **select climate scenario** with **storm surges** to generate corresponding flood hazard and risk maps
- Users can **select mitigation scenario** to assess its impact on flood hazard and risk at site level

Upstream boundary condition:

In progress : Link with HPC allowing user to launch its own scenario

User Requirements

The platform should be designed to address the specific requirements of different user groups (policymakers, researchers, environmental managers), ensuring ease of access, usability, and the ability to make data-driven decisions

Data Visualization and Analysis Tools

- Graphical tools
- Data download
- Modelling

Real-Time Data Access

- Live data feeds
- Automatic data updates
- Integrate additional/other satellite and sensor data

Support Tools for Policymakers and Managers

- Risk assessments
- Sustainability indicators
- Scenario planning tools

Integration with External Data Sources

- Data sharing
- Support integration with GIS software

Information

CoastalME (Coastal Modeling Environment) is a free, open-source software designed to help understand how coastlines change over time. It's especially useful for scientists, engineers, and planners working on coastal erosion, sediment movement, and climate adaptation.
